The University of Texas at Austin

EE 306, Fall 2011

Yale Patt, Instructor

Faruk Guvenilir, Milad Hashemi, Jennifer Davis, Garrett Galow,

Ben Lin, Taylor Morrow, Stephen Pruett, and Jee Ho Ryoo, TAs

Exam 2, November 2, 2011

Name: Solution

Problem 1 (15 points): 15

Problem 2 (10 points): 10

Problem 3 (20 points): 20

Problem 4 (15 points): 15

Problem 5 (15 points): 15

Problem 6 (25 points): 25

Total (100 points): 100

Note: Please be sure that your answers to all questions (and all supporting work that is required) are contained in the space provided.

Note: Please be sure your name is recorded on each sheet of the exam.

I will not cheat on this exam.

Solution
Signature

GOOD LUCK!

Name: Solution

Problem 1. (15 points):

Part a. (5 points): An LC-3 computer, during execution of a program, encounters during a period of 19 clock cycles the following states of the state machine in sequence:

18, 33, 35, 32, 2, 25, 27, 18, 33, 35, 32, 6, 25, 27, 18, 33, 35, 32, 1

List the opcodes of the instructions executed in the order executed. Use as many entries as you need:

LD
LDR
ADD
/
/

Part b. (5 points): Construct the symbol table for the block of code on the left:

```

        .ORIG x4000
        0 ADD    R1, R2, R3
DIVIDE 1 AND    R1, R2, R3
        2 JMP    HERE
HELP1   .BLKW 4 3, 4, 5, 6
HELP2   .STRINGZ "HELP" 7, 8, 9, A, B
HERE    C. FILL xF025
        .END

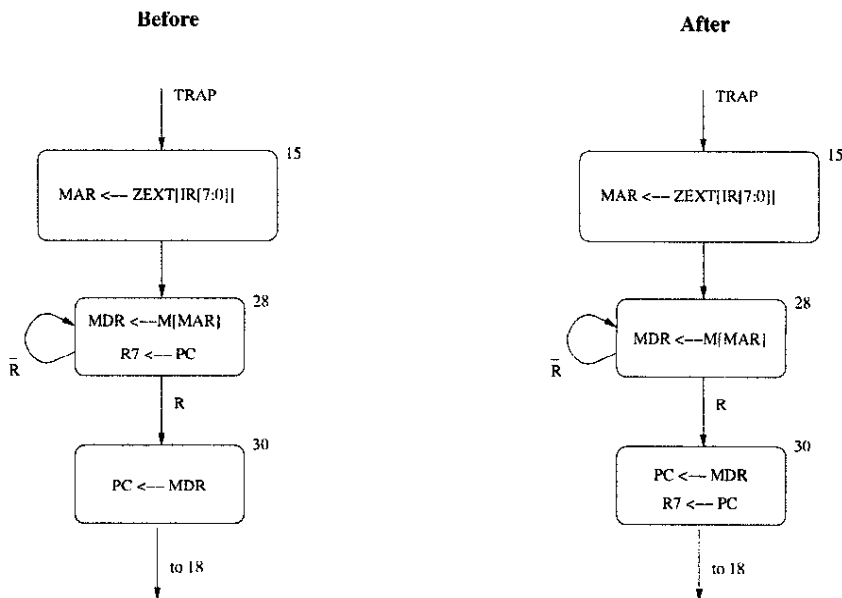

```

Symbol Table:

Symbol	Address
DIVIDE	x4001
HELP1	x4003
HELP2	x4007
HERE	x400C

Name: Solution

Part c. (5 points): The LC-3 state machine shows that after Decode (state 32), the TRAP instruction requires three clock cycles to finish execution, represented as states 15, 28, and 30. These three states are reproduced below (on the left). Note that R7 gets loaded with PC many times, depending on how many cycles it takes to read memory. A suggestion: Move $R7 \leftarrow PC$ from state 28 to state 30 so it will get done once (as shown on the right).

Will the suggested new implementation work on our existing data path? EXPLAIN in 15 words or fewer.

No, Both MDR to PC and PC to R7 would require using the Bus. Only 1 value can be gated on the Bus at a time (during a single cycle).

Name: Solution

Problem 2. (10 points): We wish to add a new TRAP service routine, which will be called by the instruction TRAP x9A. The new trap routine will wait for someone to type a lower case letter, then echo on the screen the corresponding capital letter. Assume the user will not type anything except a lower case letter. The assembly language code for this trap service routine is shown below:

```
.ORIG x2055
```

```
ST R7, B
```

```
ST R1, SaveR1
```

```
ST R0, SaveR0
```

```
TRAP x20
```

```
LD R1, A
```

```
ADD R0, R0, R1
```

```
TRAP x21
```

```
LD R7, B
```

```
LD R1, SaveR1
```

```
LD R0, SaveR0
```

```
JMP R7
```

```
SaveR1 .BLKW 1
```

```
SaveR0 .BLKW 1
```

```
A .FILL #-32
```

```
B
```

```
.BLKW 1
```

```
.END
```

Part a: In order for TRAP x9A to call this service routine, what memory location must contain what value.

Address: x009A

Value: x2055

Part b: Fill in the missing information in the assembly language program. i.e, the three missing instructions, the one missing label, and the operand of the .FILL pseudo-op.

Name: Solution

Problem 3. (20 points): The following LC-3 assembly language program:

```
        .ORIG x3000
        AND R2, R2, #0
        AND R6, R6, #0
        ADD R2, R2, #1
TOP      ADD R3, R2, #0
        ADD R4, R1, #0
SEARCH  ADD R3, R3, R3
        ADD R4, R4, #-1
        BRp SEARCH
        AND R5, R3, R0
        BRz NEXT
        ADD R6, R6, R2
NEXT     ADD R2, R2, R2
        BRzp TOP
END      ST R6, RESULT
        HALT
RESULT  .BLKW 1
        .END
```

Must be inputs

What does it do (in twenty words or fewer)? Please be BRIEF but PRECISE.

You can assume that some of the registers will already contain numbers that are relevant to the program.

Shifts the number in R0 right by the number of bit positions specified in R1, and stores the result in RESULT.

What is the function of R0? For what range of input values does the program function as you've described above?

The number to shift. Any Input Values

What is the function of R1? For what range of input values does the program function as you've described above?

How much to shift By. Positive Input Values

What is the function of R6? For what range of input values does the program function as you've described above?

Keep track of Result/output. Any Input Values.

Name: Selofan

Problem 4. (15 points): The following LC-3 assembly language program executes to completion.

```
.ORIG    x3000
AND      R0, R0, #0
ADD      R1, R0, #1
ADD      R3, R0, #10
LEA      R6, RESULTS

LOOP     ADD      R2, R0, R1
         ADD      R0, R1, #0
         ADD      R1, R2, #0

STORE    STR      R1, R6, #0

LD       R2, STORE
ADD      R2, R2, #1
ST       R2, STORE

ADD      R3, R3, #-1
BRp      LOOP

HALT

RESULTS .BLKW    10
.END
```

Part a. (9 points): After the program has halted, what values are contained (in decimal) in the ten consecutive memory locations starting at the memory location labeled RESULTS?

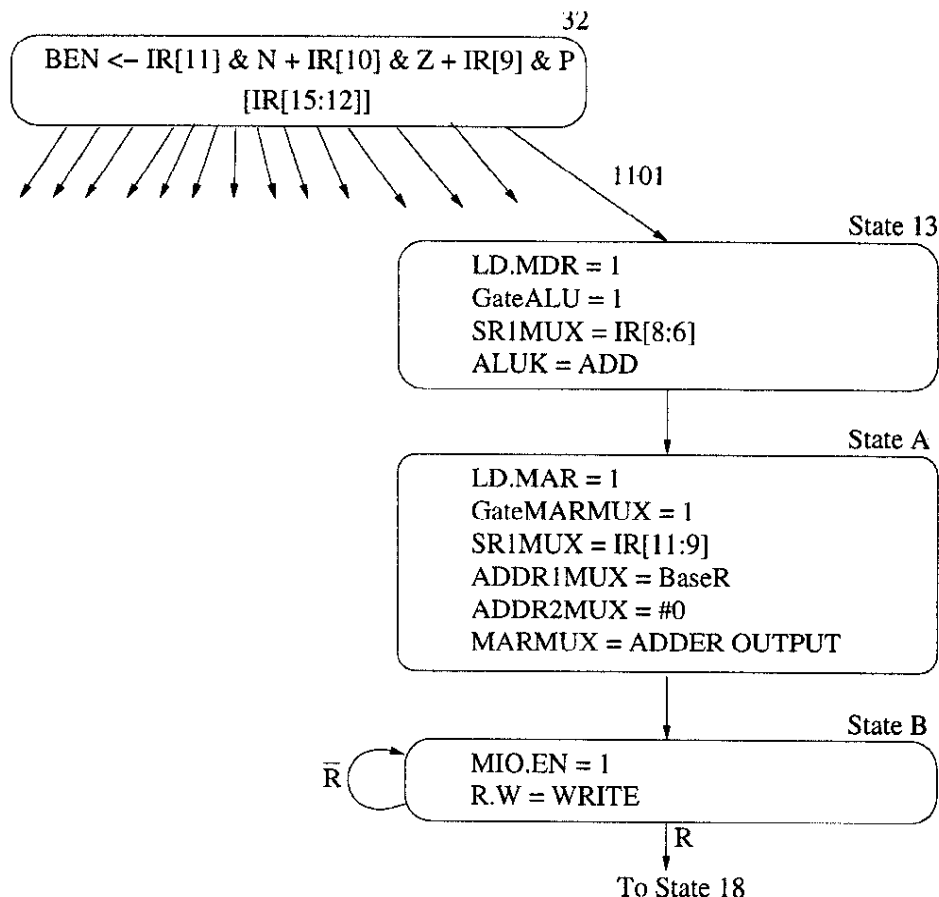

1
2
3
5
8
13
21
34
55
89

Part b. (6 points): The three instructions inside the box above can be replaced by a single instruction while preserving the functionality of the program. What is that single instruction?

ADD R6, R6, #1

Name: Solution

Problem 5. (15 points): Let's use the unused opcode 1101 to specify a new instruction. We will require 3 states after decode (state 32) to complete the job. The control signals required to carry out the work of the new instruction are shown below. All control signals not shown below are 0.

In 20 words or fewer, what does the new instruction do?

Adds the contents of SR1 (IR[8:6]) to SR2 (or immediate) and stores result in location specified by BaseR (IR[11:9]).

The instruction may have one or two potential formats. Fill out one or both as you deem appropriate.

* Full Credit for only specifying first format (IR[6]=0).

Name: Solution

Problem 6. (25 points): An LC-3 program is executing on the LC-3 Simulator when a breakpoint is encountered, and the Simulator stops. At that point, **the contents of several registers are as shown in the first row of the table**. After the run button is subsequently pushed, the next four instructions that are executed, none of which are an STI or LDI, produce the values shown in the table, **two rows of the table per instruction executed**. The first row of each pair shows the contents after the fetch phase of the corresponding instruction, and the second row of each pair after that instruction completes.

Note that some values are missing, and are presented by letters A, B, C, D, E, F, G, H, I, and J.

PC	MAR	MDR	IR	R0	R1	R2	R3	R4	R5	R6	R7
x1800	x7FFF	x2211	xBFFE	x31FF	x2233	x5177	x3211	x21FF	x5233	x3177	x2211

Table A.2 Service Routines

Trap Vector	Assembler Name	Description
x20	GETC	Read a single character from the keyboard. The character is not echoed onto the console. Its ASCII code is copied into R0. The high eight bits of R0 are cleared.
x21	OUT	Write a character in R0[7:0] to the console display.
x22	PUTS	Write a string of ASCII characters to the console display. The characters are contained in consecutive memory locations, one character per memory location, starting with the address specified in R0. Writing terminates with the occurrence of x0000 in a memory location.
x23	IN	Print a prompt on the screen and read a single character from the keyboard. The character is echoed onto the console monitor, and its ASCII code is copied into R0. The high eight bits of R0 are cleared.
x24	PUTSP	Write a string of ASCII characters to the console. The characters are contained in consecutive memory locations, two characters per memory location, starting with the address specified in R0. The ASCII code contained in bits [7:0] of a memory location is written to the console first. Then the ASCII code contained in bits [15:8] of that memory location is written to the console. (A character string consisting of an odd number of characters to be written will have x00 in bits [15:8] of the memory location containing the last character to be written.) Writing terminates with the occurrence of x0000 in a memory location.
x25	HALT	Halt execution and print a message on the console.

Table A.3 Register Assignments

Address	I/O Register Name	I/O Register Function
xFE00	Keyboard status register	Also known as KBSR. The ready bit (bit [15]) indicates if the keyboard has received a new character.
xFE02	Keyboard data register	Also known as KBDR. Bits [7:0] contain the last character typed on the keyboard.
xFE04	Display status register	Also known as DSR. The ready bit (bit [15]) indicates if the display device is ready to receive another character to print on the screen.
xFE06	Display data register	Also known as DDR. A character written in the low byte of this register will be displayed on the screen.
xFFFE	Machine control register	Also known as MCR. Bit [15] is the clock enable bit. When cleared, instruction processing stops.
